## *Precision Hall-Effect Angle Sensor IC*

---

### **Not for New Design**

This part is in production but has been determined to be NOT FOR NEW DESIGN. Sale of this part is currently restricted to existing customer programs already using the part. The part should not be purchased for new programs or designed into new applications. Samples are no longer available.

Date of status change: December 5, 2016

#### **Recommended Substitutions: [A1338 Family](#)**

*For existing customer transition, and for new customers or new applications, contact Allegro Sales.*

---

NOTE: For detailed information on purchasing options, contact your local Allegro field applications engineer or sales representative.

# Precision Hall-Effect Angle Sensor IC

## FEATURES AND BENEFITS

- Automotive AEC-Q100 qualified
- Contactless 0° to 360° angle sensor IC, for angular position, rotational speed, and direction measurement
- Available with either a single die or dual independent die housed within a single package
- Circular Vertical Hall (CVH) technology provides a single-channel sensor system, with air-gap independence
- 12-bit resolution possible in low RPM mode, 10-bit resolution in high RPM mode
- Angle Refresh Rate (output rate) configurable between 25 and 3200  $\mu$ s through EEPROM programming
- Capable of sensing magnet rotational speeds in excess of 7600 rpm
- SPI interface allows use of multiple independent sensors for applications requiring redundancy
- EEPROM programmable angle reference (0°) position and rotation direction (CW or CCW)
- Absolute maximum  $V_{CC}$  of 26.5 V for automotive battery-powered applications

## Packages:

*Not to scale*

Single SoC

14-pin TSSOP (LE package)

Dual Independent SoCs

24-pin TSSOP (LE package)

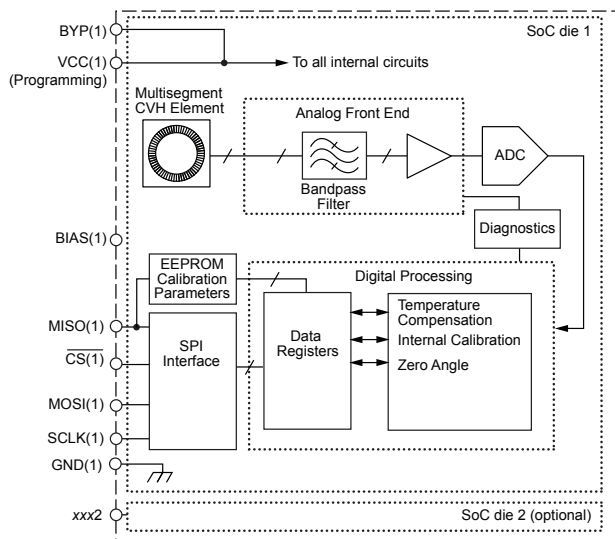

## DESCRIPTION

The A1334 is a 360° angle sensor IC that provides contactless high-resolution angular position information based on magnetic Circular Vertical Hall (CVH) technology. It has a system-on-chip (SoC) architecture that includes: a CVH front end, digital signal processing, and a digital (SPI) output. The A1334 is ideal for automotive applications requiring high-speed 0° to 360° angle measurements, such as electronic power steering (EPS) and throttle systems.

The A1334 supports a Low RPM mode for slower rate applications and a High RPM mode for high-speed applications. High RPM mode is for applications that require higher refresh rates to minimize error due to latency. Low RPM mode is for applications that require higher resolution operating at lower angular velocities.

As part of its signal processing functions, the A1334 includes automotive-grade temperature compensation to provide accurate output over the full operating temperature and voltage ranges. The A1334 also includes EEPROM technology for end-of-line calibration.

The A1334 is available as a single die in a 14-pin TSSOP, or dual die in a 24-pin TSSOP. Both packages are lead (Pb) free with 100% matte-tin leadframe plating.

**OPERATING CHARACTERISTICS (continued): valid over the full operating voltage and ambient temperature ranges, unless otherwise noted**

Characteristics	Symbol	Test Conditions	Min.	Typ. <sup>1</sup>	Max.	Unit <sup>2</sup>
<b>Angle Characteristics (continued)</b>						
Angle Error <sup>15</sup>	ERR <sub>ANG</sub>	T <sub>A</sub> = 25°C, ideal magnet alignment, B = 300 G, target rpm = 0	–	±0.6	–	degrees
		T <sub>A</sub> = 150°C, ideal magnet alignment, B = 300 G, target rpm = 0	–1.75	–	1.75	degrees
Angle Noise <sup>16, 19</sup>	N <sub>ANG</sub>	T <sub>A</sub> = 25°C, B = 300 G, no internal filtering	–	0.2	–	degrees
		T <sub>A</sub> = 150°C, no internal filtering, B = 300 G, target rpm = 0	–	0.27	–	degrees
Temperature Drift	ANGLE <sub>DRIFT</sub>	T <sub>A</sub> = –40°C, B = 300 G	–	±1.5	–	degrees
		T <sub>A</sub> = 150°C, B = 300 G	–1.5	–	–1.5	degrees
Angle Drift Over Lifetime <sup>17</sup>	ANGLE <sub>DRIFT-LIFE</sub>	B = 300 G, typical maximum drift observed after AEC-Q100 qualification testing	–	±1.0	–	degrees

<sup>1</sup> Typical data is at T<sub>A</sub> = 25°C and V<sub>CC</sub> = 5 V, and it is for design estimates only.

<sup>2</sup> 1 G (gauss) = 0.1 mT (millitesla).

<sup>3</sup> At power-on, a die will not respond to commands until V<sub>CC</sub> rises above V<sub>UVLOHI</sub>. After that, the die will perform and respond normally until V<sub>CC</sub> drops below V<sub>UVL</sub>.

<sup>4</sup> LOW.

<sup>4</sup> Characterization data shows negligible accuracy degradation at supply voltages between 4.35 V and 4.50 V. Significant degradation in accuracy may occur below 4.30 V.

<sup>5</sup> VCC Low Threshold Flag will be sent via the SPI interface as part of the angle measurement.

<sup>6</sup> During the power-on phase, the A1334 SPI transactions are not guaranteed.

<sup>7</sup> Each die includes a linear regulator. The output voltage and current specifications are to aid in PCB design. The pin is not intended to drive any external circuitry.

<sup>8</sup> Parameter is not guaranteed at final test. Values for this characteristic are determined by design.

<sup>9</sup> The A1334 operates in magnetic fields lower than 300 G, but with reduced accuracy and resolution.

<sup>10</sup> Contact Allegro for field optimization. In general, operation with larger magnetic field values result in improved performance (see Figures 3 and 4).

<sup>11</sup> RES<sub>ANGLE</sub> represents the number of bits of data available for reading from the die registers.

<sup>12</sup> Effective Resolution is calculated using the formula below:

$$\log_2(360) - \log_2\left(\sum_{l=1}^{32} \sigma_l\right)$$

where  $\sigma$  is the Standard Deviation based on thirty measurements taken at each of the 32 angular positions,  $l = 11.25, 22.5, \dots, 360$ .

<sup>13</sup> The rate at which a new angle reading will be ready.

<sup>14</sup> To calculate Low RPM mode, time =  $25 \times 2^{AVG}$ . Given AVG = 011 = 3 (decimal), so  $2^3 = 8$ .

<sup>15</sup> In general, Allegro's angle sensor ICs are more accurate when stronger magnetic fields (i.e. 900 G) are used. Please contact Allegro for information regarding how users can realize higher accuracy performance from Allegro's angle sensor ICs by using stronger magnetic fields.

<sup>16</sup> Value reflects 3 standard deviations.

<sup>17</sup> After qualification testing, a typical IC drifted less than 0.5 degrees; however, after certain long duration stresses (for example 1000 cycles of –65 to 175 degree C temperature cycling), a small number of devices drifted by approximately 1.5 degrees.

<sup>18</sup> Maximum value based on worst case simulations.

<sup>19</sup> One sigma value at 300 G. Operation with a larger magnetic field results in improved noise performance. For 600 G operation noise reduced by 50% vs 300 G.

**Definition of Response Time**

## FUNCTIONAL DESCRIPTION

### Operational Modes

The A1334 angle sensor device is designed to support a wide variety of automotive applications requiring measuring 0° to 360° angle positions.

An option for two electrically-independent die in the same package provides solid-state consistency and reliability. Each die SPI port can be configured in a different RPM mode. The data output selection is controlled by the address request in the SPI Read command.

The A1334 has dual identical system-on-chip (SoC) architecture. The output of each die is used by the host microcontroller to provide a single channel of target data.

### Angle Measurement

The A1334 can monitor the angular position of a rotating magnet at speeds ranging from 0 to more than 7600 rpm. At lower rotational speeds, the A1334 provides high-resolution angle measurement accuracy. It can also support higher rates of rotational speeds at reduced levels of angle measurement accuracy.

The A1334 can be configured to operate in two angular measurement modes of operation: Low RPM mode, and High RPM mode. For applications that have a speed range from 0 to 500 rpm (can vary with AVG), the Low RPM mode provides increased resolution. For applications above 500 rpm, configuring the A1334 in High RPM mode provides angle measurements with standard resolution. Above 7600 rpm, the A1334 continues to provide angle data; however, the accuracy is proportionally reduced.

The actual update rate of Low RPM mode can be changed by setting the AVG bits in the EEPROM. (See the appendix *Programming Reference* for details.) The selection of Low RPM mode or High RPM mode can be programmed, via the Angle\_Meas\_Mode bit, for the expected maximum rotational speed of the magnet in operation to provide the highest corresponding level of angle accuracy. However, the A1334 provides valid output data regardless of the selected mode and the application speed.

Although the range of the resolution of the measurement data output, RES<sub>ANGLE</sub>, is determined by the selection of either High RPM or Low RPM mode, the measurement is also affected by the intensity (B, in gauss) of the applied magnetic field from the target. At lower intensities, a reduced signal-to-noise ratio will cause one or two LSBs to change state randomly due to noise,

and the effective DAC resolution is reduced. These factors work together, so when High RPM mode is selected, the effective range of resolution is 8 to 10 bits (from lower to higher field intensities), and in Low RPM mode, the effective range is 11 to 12 bits, depending on field strength and AVG selection.

Regardless of the field intensity and mode selection, the transmission protocol and number formatting remains the same. The MSB is always transmitted first. The entire number should be read.

The Output Angle is always calculated at maximum resolution. To be more explicit:

$$Angle_{OUT} = 360 (^{\circ}) \times D[12:0] / (2^{13}) \quad (1)$$

This formula is always true, regardless of the applied field intensity. What changes with the field and speed setting is how uniform the LSBs of the measurement data (D 12:x) will be.

When using the dual die version of the A1334, it should be noted that the secondary die (E2) is rotated 180° relative to the primary die (E1). This results in a difference in measurement of approximately 180° between the two die, given perfect alignment of each die to the target magnet.

This phenomenon can be counteracted by subtracting the offset using a microprocessor. Alternatively, the difference between the two die can be compensated for using the EEPROM for setting the Reference Angle.

### System-Level Timing

The A1334 outputs a new angle measurement every t<sub>ANG</sub> μs. In High RPM mode, the A1334 outputs a new angle measurement every t<sub>ANG</sub> μs, with an effective resolution of 10 bits. There is, however, a latency of t<sub>LAT</sub>, from when the rotating magnet is sampled by the CVH to when the sampled data has been completely transmitted over the SPI interface. Because an SPI interface Read command is not synchronous with the CVH timing, but instead is polled by the external host microcontroller, the latency can vary. For single back-to-back SPI transactions (first transaction is sending the Read register 0x0 command, second is retrieving the angle data) the following scenarios are possible:

- Worst case: 2 CVH cycle + 2 SPI cycles
- Best case: 1.5 SPI cycles; 2 μs, assuming a 10 MHz SPI clock

## Power-Up

Upon applying power to the A1334, the device automatically runs through an initialization routine. The purpose of this initialization is to ensure that the device comes up in the same predictable operating condition every power cycle. This initialization routine takes a finite amount of time to complete, which is referred to as Power-On Time,  $t_{PO}$ .

The A1334 wakes up in a default state that sets all SPI registers to their default value. It is important to note that, regardless of the state of the device before a power cycle, the device will re-power with default values. For example, on every power-up, the device will power up in the mode set in the EEPROM bit RPM. The state of the EEPROM is unchanged.

## Diagnostics

The A1334 supports a number of on-chip self-diagnostics to enable the host microcontroller to assess the operational status of each die. For example, the A1334 can detect a low supply voltage and includes an onboard watchdog timer to monitor that internal clocks are running properly.

**Table 1: Diagnostic Capabilities**

Diagnostic/ Protection	Description	Output State
Reverse VCC	Current Limiting (VCCx pin)	
Output to VCC	Current Limiting (MISOx pin)	
Output to Ground	Current Limiting (MISOx pin)	
Watchdog	Monitors digital logic for proper function	IERR Error flag is set
Missing Magnet	Monitors magnet field level in case of mechanical failure	MAGM Error flag is set
EEPROM Error Detection and Correction	Detection and correction of certain EEPROM memory bit errors	Error flags set in SPI message when errors are detected or corrected
Loss of VCC	Determine if battery power was lost	BATD Error flag is set
Redundancy	Dual die version of the A1334 provides redundant sensors in the same package	

**Undervoltage Lockout and VCC Low Flag Diagnostic**

The MISO pin state changes according to the state of the VCC ramp, as shown in Figure 1.

Figure 1: Relationship of VCC and MISO Output

## APPLICATION INFORMATION

### Calculating Target Zero Degree Angle

When shipped from the factory, the default angle value when orientated as shown in Figure 2, is approximately 40° (220° on secondary die). In some cases, the end user may want to program an angle offset in the A1334 to compensate for variation in magnetic assemblies, or for applications where absolute system-level readings are required.

The internal algorithm for computing the output angle is as follows:

$$Angle_{OUT} = Angle_{RAW} - Reference\ Angle \quad (2)$$

The procedure to zero out the A1334 is quite simple. During final application calibration and programming, position the magnet above the A1334 in the required zero-degree position, and read the angle from the A1334 using the SPI interface ( $Angle_{OUT}$ ). From this angle, the Reference Angle required to program the A1334 can be computed as follows:

$$Reference\ Angle = Angle_{OUT} \quad (3)$$

### Bypass Pin Usage

The Bypass pin is required for proper device operation and is intended to bypass internal IC nodes of the A1334. A 0.1 μF capacitor must be placed in very close proximity to the Bypass pin. It is not intended to be used to source external components. To assist with PCB layout, please see the Operating Characteristics table for output voltage and current requirements.

### Changing Sampling Modes

The A1334 features a High RPM sampling mode, and a Low RPM sampling mode. The default power-on state of the A1334 is loaded from EEPROM. To configure the A1334 to Low RPM mode, set the Operating mode to Low RPM mode by writing a logic 1 to bit 2 (RPM) of the configuration commands (CTRL) register, via the SPI interface.

**Figure 2: Orientation of Magnet Relative to Primary Die and Secondary Die**  
(dual die version used as example)

**Magnetic Target Requirements**

The A1334 is designed to operate with magnets constructed with a variety of magnetic materials, cylindrical geometries, and field strengths, as shown in Table 2. To reach this end, Allegro offers three different “Field Optimization” or trim levels; 300 G, 550 G and 900 G. Figure 8 demonstrates the typical 25°C performance for these three trim levels over field strength. In general, higher field strengths result in improved performance in terms of angle error and angle noise (see Figures 3 and 4) To obtain maximum performance, it is important to match the operating field with the field trim level. Contact Allegro for more detailed information on magnet selection and performance.

**Redundant Applications and Alignment Error**

The A1334 dual die version is designed to be used in redundant applications with a single magnet spinning over the two separate dies that are mounted side-by-side in the same package. One challenge with this configuration is correctly lining up the magnet with the device package, so it is important to be aware of the physical separation of the two dies. Figure 5 depicts two possible

alignment configurations.

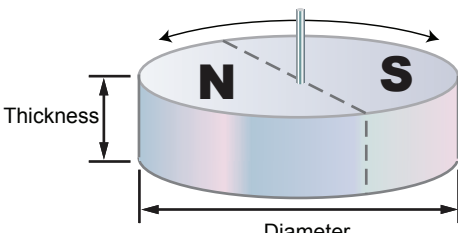

Figure 6 illustrates the behavior of alignment error when using an 8 mm diameter magnet positioned above the branded face of the package. The curve shows the relationship between absolute angle error present on the output of the die versus eccentricity of the die relative to the rotation axis of the magnet. The curve is the same for both dies in the package.

The curve provides guidance to determine what the optimal magnet placement should be for a given application. For example, given that the maximum spacing between the two dies is 1 mm, if the center of the magnet rotation is placed at the midpoint between the two dies, each die will have a maximum eccentricity of 0.5 mm.

For applications with reduced accuracy requirements, considering one die the primary and the other die the secondary, the magnet axis of rotation could be positioned directly above the primary die, and thus offset 1 mm from the secondary die, yielding zero alignment error on the primary die, and approximately  $\pm 1^\circ$  of absolute error on the secondary die due to geometric mismatch.

**Table 2: Typical Target Magnet Parameters**

Diameter (mm)	Thickness (mm)
15	4
10	2.5
8	2.5
6	2.5

\*A magnet with 8 mm (or greater) diameter and 2.5 mm thickness is the recommended magnet for redundant applications.

**Figure 3: Maximum Peak Angle Error Over Field Strength Different Factory Optimizations**

**System Timing and Error**

The A1334 is a digital system, and therefore takes angle samples at a fixed sampling rate. When using a sensing device with a fixed sampling rate to sample a continuously moving target, there will be error introduced that can be simply calculated with the sampling rate of the device and the speed at which the magnetic

signal is changing. In the case of the A1334, the input signal is rotating at various speeds, and the sampling rate of the A1334 is fixed at ANG. The calculation would be:

$$ANG (\mu s) \times angular\ velocity (\text{°}/\mu s) \quad (4)$$

So the faster the magnetic object is spinning, the further behind in angle the output signal will seem for a fixed sampling rate.

## EMC Reduction

For applications with stringent EMC requirements, a 100 Ω resistance should be added to the supply for the device in order to suppress noise. A recommended circuit is shown in Figure 16.
